## PLATE XXV.

### TRINGA VANELLUS.

LAPWING, or TEWIT.

G R A L L Œ.

Bill roundish. Tongue entire, fleshy. Thighs naked. Toes divided.

#### GENERIC CHARACTER.

Bill roundish, strait, about the length of the head. Nostrils narrow; Toes four.

#### SPECIFIC CHARACTER.

Bill, Crown, Crest, Throat, black; a black line under each Eye; at the back part of the Head a Crest of about twenty narrow feathers of unequal length; sides of the Neck white; fore part as far as the Breast black; the Back and Wings green, most beautifully glossed with fine purple, brown and blue. Quills black. Breast and Belly white. Upper Tail Coverts and Vent pale rufous. Tail white from the base half up, extreme half black. Legs red.

*Tringa Vanellus.* Pedibus rubris, crista dependente, pectore nigro.

*Fn. Suec.* 148.—*Linn. Syst. Nat. Editio Decima.*

*I.* 148.

*Scop. Ann.* 1. N° 141.

*Brun.* N° 170.

A 2

*Mull.*

# PLATE XXV.

Wipa, Kowipa, Blæcka. *Faun. Suéc. Sp. 176.*

Danis Vibe, Kivit. *Brunnich. 170.*

The length of this species is about thirteen inches and a half; the breadth more than two feet; the weight eight ounces; the female is exactly like the male both in form and colour, but is rather smaller.

## PLATE XXV.

It lays four eggs, of a dirty olive cast, speckled with black \*, in a slight nest composed of bents, or on a bed of dried grafs, scraped together on the ground; the hen fits about three weeks; the young as soon as hatched run together like chickens.

The old birds shew a remarkable sollicitude for their young, flying with great anxiety about them if disturbed; and using every stratagem to decoy the disturber from the nest; feigning to flutter as if wounded on the ground at a little distance, or running along as if lame: should these artifices prove useless they become desperate, and will strike at the person or animal whom they cannot entice away.

Towards winter both young and old assemble in flocks of four or five hundred on the heaths or marshy places, at which time they are caught in nets for the use of the table in the same manner that *Ruffs* are.

They are common in most parts of *Europe*, as far as *Iceland*; change place according to the season; are met with in *Persia* and *Egypt* in winter, and *Latham* says he has seen a specimen from *China*.

They are esteemed a delicacy as their nourishment is only slugs and worms; these they draw out of the ground morning and evening. They are sometimes kept in gardens, and by good treatment become both useful and familiar.

---

\* Pennant observes that "the eggs are held in great esteem for their delicacy; and are sold by the *London* Poulterers for three shillings the dozen."

# PLATE XXVI.

## PARUS CRISTATUS.

### CRESTED TITMOUSE.

#### PASSERES.

Bill conic, pointed. Nostrils oval, broad, naked.

#### GENERIC CHARACTER.

Bill short, strong, entire, bristles at the base. Tongue blunt, with bristles at the end.

#### SPECIFIC CHARACTER.

Forehead and sides of the Head white; on the head a crest of black pointed feathers with white edges. Chin and Throat black; with a collar of the same colour bounding the Cheeks. Back, Wings, and Tail, rufous grey. Under parts of the Body white, sides with a rufous tinge. Legs lead colour.

*Buff. Ois.* V. p. 447.—*Pl. Enl.* 502. f. 2.

---

The Crested Titmouse is so very rarely found in this country, that neither *Latham* or *Pennant* has described it as a British species; nor has the latter included it in the Appendix of the British Zoology, among the foreign birds which visit us at unstated periods.

It is met with in many parts of *France*, particularly in *Normandy*, and the intermediate country between that and *Sweden*; writers concur that it is of a very solitary disposition, never mixing with other birds, nor in numbers even with its own species; it is chiefly found among the ever-green trees in the deep and gloomy recesses of extensive forests, and is therefore little known even in those parts where the species is most frequent.

*Walcot* mentions that they are sometimes seen in *Scotland*, and once visited that country in a large flock; the specimen from which our figure is copied was shot in *Scotland* also, in company with several others in the year 1792.

## PLATE XXVII.

### EMBERIZA NIVALIS?

#### TAWNY BUNTING.

#### PASSERES.

Bill conic, pointed. Nostrils oval, broad, naked.

#### GENERIC CHARACTER.

Bill conic, angular on each side; a hard knob within the upper mandible.

#### SPECIFIC CHARACTER.

Bill yellow tip with black. Head and round the Neck tawny. Back brown, marked with black. Legs black. Rump tawny. Tail twelve feathers, rather forked, exteriors white.

EMBERIZA NIVALIS *Faun. Suec.* 227. B.

EMBERIZA FRIGIDA. *Lath. Cat. English Birds, Suppl.*

TAWNY BUNTING. *Pen. Br. Zool.* 121.

GREAT PIED MOUNTAIN FINCH or BRAMBLING. *Will. Orn.* 225.

L'Ortolan de Neige, Hortulanus Nivalis. *Brif. av.* III. 285.

Schnee-ammer (Snow-hammer). *Frisch.* I. 6.

---

These birds are sometimes met with in the northern parts of England, but are not common; three males and one female were shot in the garden of Mr. Slade, Vauxhall-road, about a fortnight since. I care-

## PLATE XXVII.

fully examined them, and found they varied very much in their colours; it is not indeed surprising that the accurate Linnæus should consider the Tawny and Mountain Buntings with their varieties, as the Snow Bunting in its different approaches to its summer appearance.

Pennant is of a different opinion, and has described it under the English name Tawny Bunting, as a distinct species. Latham has also described it as a different species in his general Synopsis; and in the list of the Birds of Great Britain, in the supplemental volume, he adds "*EMBERIZA FRIGIDA*," and refers to the description of the Tawny Bunting in the British Zoology, N<sup>o</sup> 121.

The name "*Emberiza glacialis*" has been also given to the same, or a mere variety of this bird.

Our specimens are about six inches and three quarters in length, twelve inches and three quarters in breadth; weight an ounce.

## PLATE XXVIII.

### COLYMBUS TROILE.

#### FOOLISH GUILLEMOT.

##### ANSERES.

Bill obtuse, covered with a thin membrane; broad, gibbous below the base, swelled at the apex. Tongue fleshy. Legs naked. Feet webbed, or finned.

##### GENERIC CHARACTER.

Bill straight, slender, pointed. Nostrils linear, at the base of the bill. Legs near the tail. Feet webbed.

##### SPECIFIC CHARACTER.

Bill black. Inside of the mouth yellow. Tips of the small quills; breast, and belly white. The rest deep mouse colour.

COLYMBUS TROILE. *Linn. Syst. I. p. 220.*

2.—*Fn. Sv. N° 149.*

*Brun. N° 108.*

*Mull. N° 152.*

*Frisch. t. 185.*

##### GUILLEMOT, or SEA HEN.

*Lonruvia Hoieri. Raii. Syn. p. 120. A. 4.*

*Will. Orn. p. 324. pl. 65.*

*Albin. I. pl. 84.*

*Edw. pl. 359. Fig. I.*

## P L A T E XXVIII.

FOOLISH GUILLEMOT. *Br. Zool.* N° 234.

*Arch. Zool.* N° 436.

*Br. Mus.*—*Lev. Mus.*

THE LAVY. *Martin's Voyage, St. Kilda,* 32.

Le Guillemot. *Brif. Orn.* VI. p. 70. i. pl. 6. fig. 1.

*Buff. Oif.* 9. p. 350. pl. 25.—*Pl. Enl.* 903.

Lommia. *N. Com. Petr.* IV. 414.

Sea-Taube, or Groenlandischer Taucher. *Frisch.* II. 185.

The Guillemot is found in immense numbers on several of the English coasts in summer; they continue in the Orkneys\* the whole year; chiefly breed in the uninhabited *Isle of Priestholm*, near the *Isle of Anglesea*; the *Farn Isles* near the coast of Northumberland, and among the high cliffs in the neighbourhood of *Scarborough*†, Yorkshire. Like the Auk, (which are also found with them in vast numbers). They lay only one egg, more than three inches in length, of a blueish white or pale sea-green colour, most elegantly streaked with black lines crossing each other in every direction.

They are very silly; for though they see their companions killed by their side, they only make a short circuit, and alight in the same place to be shot at in turn.

Our bird is seventeen inches in length, weight twenty-five ounces, breadth twenty-seven inches and a half. *Brunnich* mentions a variety,

\* *Penn. Br. Zool.*

† *Willoughby.*

## P L A T E XXVIII.

with a broader and shorter bill, and yellow margins. *Muller* speaks of a variety, with a white ring round the eyes, and a line of the same colour behind.

They are found in most of the northern parts of Europe to *Spitzbergen* †, the coast of *Lapmark*, along the *White* and *Icy Sea* to *Kamtschatka*; are found at *Newfoundland* and in some parts of *North America*.

It is called *Guillem* by the Welch, *Guillemot* or *Sea Hen*, at *Northumberland* and *Durham*; in the southern parts, *Willocks*.

---

† Both *Pennant* and *Latham* has separated the *Guillemots* from the *Divers*, and *Grebes*; to the first *Latham* has given the generic title *Uria* after *Briffon*; the second he continues under the *Linnæan* genus (*Colymbus*); and the third he calls *Podiceps*.

## P L A T E   XXIX.

### COLYMBUS AURITUS.

E A R E D   G R E B E .

A N S E R E S .

Bill obtuse, covered with a thin membrane, broad, gibbous below the base, swelled at the apex. Tongue fleshy. Legs naked. Feet finned, or webbed.

#### GENERIC CHARACTER.

Bill straight, slender, pointed. Nostrils linear, at the base of the bill. Legs near the tail. Feet webbed.

#### SPECIFIC CHARACTER.

Bill curved a little upwards at the point. Lore and irides crimson. Head black, with an orange-coloured tuft of feathers behind each eye. Breast silvery white. Ridge and tips of the wings white. Legs olive.

COLYMBUS AURITUS. *Linn. Syst. I. p. 222. 8.*

*Fn. Sv. 152.*

La Grebe à oreilles. *Brif. Orn. 6. p. 54. 6.*

## PLATE XXIX.

Le petit Grebe huppé. *Buff. Ois.* 8. p. 235.

*Novægis* Sav-Orre, Soe-Orre.

*Bornholmis* Soe-Hoene.

*Islandis* Flauekitt. *Brun.* 136.

---

The length of this Species is twelve inches; they inhabit the fens near Spalding, where they breed; they are found in the northern parts of Europe, and in the temperate parts of Siberia and Iceland. Said by *Bougainville* to be met with in *Falkland Islands*, where it is called the *Diver with Spectacles*.—*Boug. Voy.* p. 61.

The nest, like most others of the same Genus, is composed of twigs, roots and stalks of water-plants, and is usually found floating among the reeds and flags, nearly filled with water. The female lays four or five small white eggs, which are hatched in the water.

# PLATE XXX.

## FALCO APIVORUS.

### HONEY BUZZARD.

#### ACCIPITRES.

Birds of prey. Bill and claws strong, hooked. An angle in each margin of the upper mandible. Body muscular. Females larger and more beautiful than the males.

#### GENERIC CHARACTER.

Bill arched from the base, which is covered with a wax-like membrane, or cere.

#### SPECIFIC CHARACTER.

Bill and Cere black. Legs yellow; Claws black. Head ash-coloured. Back and Wings dark brown. Breast and Belly white, spotted. Tail barred.

FALCO APIVORUS, Cere nigra, pedibus feminudis flavis,

*Pl. enl. 420.*

Le Goiran, ou Bondrée. *Belon av. 101.*

Frosch-geyerl. *Kram. 331.*

Slag-Hok. *Faun Suec. sp. 65.*

Muse-Hoeg, Muse-Baage. *Brun. p. 5.*

Though the Honey Buzzard inhabits various parts of the continent of Europe it is no where common except in the open parts of *Russia* and *Siberia*; is seen as far north as *Sondonor* in *Norway*. In England it is scarcely ever met with.

The length of our Specimen is twenty-three inches; weight when taken thirty ounces. In its colours it precisely corresponds with the description of the Honey Buzzard in *Latham's General Synopsis of Birds*, but differs very materially from that either of *Linnæus* \*, *Briffon* †, *Pennant* ‡, or *Albin* ||.

*Albin* says, "This bird builds its nest of small twigs, laying on them wool, and upon the wool its eggs. Some of them have been found to

\* *Linnæus* describes the tail with only one cinerous band, the tip white

† *Briffon* says "the side tail-feathers are banded with white on the inner webs, and are spotted with brown."

‡ *Albin* describes the tail of his specimen "plain without bars."

|| *Pennant*, in the *Br. Zool.* describes the Honey Buzzard, "Chin, breast, and belly white; the two last marked with dusky spots, pointing downwards; and three dusky bars on the tail." He mentions a variety "entirely of a deep brown; had much the same marks on the wings and tail as the male; and the head tinged with ash-colour."

## PLATE XXX.

make use of an old nest of a kite to breed in, feeding their young with the *nymphæ of wasps*, the combs of wasps being found in the aforesaid nests, in which were two young ones, covered with a white down, spotted with black; their feet of a pale yellow, their bills between the nostrils and the head white, their claws large: in the crops were found lizards, frogs, &c. In one of them were found two lizards entire, with their heads towards the bird's mouth, as if they sought to creep out."—"This bird runs very swiftly like a hen."—*Alb. 1. t. 2.*

The eggs of the Honey Buzzard are variously described by different authors; the specimens formerly preserved in the Portland Museum were of a very deep red brown, with ferruginous blotches of chestnut; *Mr. Latham* says he was informed by *Mr. Boys*, "that they are of a blueish white, marked with irregular rufous spots; the shape of the egg almost globular; usually three in the nest." *Mr. Pennant* says he was favoured with a description of the eggs by *Mr. Plumly*; "they were blotched over with two reds, something darker than those of the Kestrel."

# PLATE XXXI.

## LANIUS COLLURIO.

RED-BACKED SHRIKE,

BUTCHER-BIRD, or FLUSHER.

ACCIPITRES.

Birds of prey. Bill and claws strong, hooked. An angle in each margin of the upper mandible. Body muscular. Females larger and more beautiful than the males.

### GENERIC CHARACTER.

Bill hooked towards the end, with a notch near the tip of the upper mandible; base not furnished with a cere. Tongue jagged at the end.

### SPECIFIC CHARACTER.

Bill black. A black stroke through the eyes. Head light grey. Upper parts of the back, and wing coverts, ferrugineous. Breast, belly, and sides, blossom-coloured. Legs black. Tail black; all the feathers, except the two middle ones, more or less white at the base.

LANIUS COLLURIO. Cauda subcuneiformi, dorso griseo, rectricibus quatuor intermediis unicoloribus, rostro plumbeo.—*Lin. Syst. Nat.* 1. 94. 3. edit. 12.

Bufferola, Ferlotta rossa. *Zinan. 91.*

Mali Sokrakoper. *Scopoli, N° 19.*

The length of this Species is seven inches and a half, breadth eleven inches; the female is of a dull ferruginous, mixed with grey: the breast, belly, and sides, dirty white, crossed with semicircular dusky lines: the tail deep brown, except the outer feather on each side, whose exterior webs are white; the female is rather larger than the male.

## PLATE XXXI.

It visits this country in the spring and departs in autumn; it is common in *France* and *Italy*, as well as in the temperate parts of *Russia*.

It builds its nest in a hedge or low bush, and lays six white eggs, encircled at the largest end with a rufous brown circle; it not only feeds on insects, but will devour the young of other birds, taking hold of them by the neck and strangling them, then tearing out the eyes, brain, &c. and when satisfied sticks the remainder on a thorn for another meal; when confined in a cage it will do the same against the wires with beetles, grasshoppers, or pieces of sheep's kidney.

It is said to imitate well the notes of other birds, though it has none of its own.

# PLATE XXXII.

## TRINGA CINCLUS.

OX-EYE, PURRE,

OR

STINT.

GRALLÆ.

Bill roundish. Tongue entire, fleshy. Thighs naked. Toes divided.

### GENERIC CHARACTER.

Bill roundish strait, about the length of the head. Nostrils narrow. Toes four.

### SPECIFIC CHARACTER.

Bill slender, black. Head, neck, back and tail, ash-coloured, or brown with dark spots. Breast, belly, and lower parts of the quill feathers white. Legs greenish brown.

*Belon av.* 213.

*Buff. Ois.* 7. p. 548.—*Pl. enl.* 851.

Giarolo. *Aldr. av.* 3. 188.

Length seven inches and a half; extent fourteen inches; weight an ounce and a half.

This Species is very common in most parts of *Europe*, and is said to be found at the *Cape of Good Hope*; in *Jamaica* and other West-India Islands. They frequent our coasts in the winter in vast flocks, alternately swimming and flying in large circles with the greatest regularity: they leave our shores in spring, and retire to some unknown place to breed. *Mr. Latham* suspects that they breed on the coast of *Kent*, having received some birds which scarcely differed from the description, from *Mr. Boys* of *Sandwich*; they were shot at *Romney*, in the month of August.

*Le Cincle* of *Buffon* and *L'Allouette de Mer à Collier* of *Brisson* has much affinity to this Bird, and is supposed to be only a difference of sex or age, as they are often taken in company.

# PLATE XXXIII.

## CORACIAS GARRULA.

### GARRULOUS ROLLER.

P I C Æ.

Bill compressed, convex.

#### GENERIC CHARACTER.

Bill strait, bending towards the tip, edges cultrated. Nostrils narrow and naked.

#### SPECIFIC CHARACTER,

AND

#### SYNONYMS.

Head, neck, breast, and belly light bluish green. Back and scapulars reddish brown; tail forked; black, blue and green. Legs dirty yellow.

On the authority of Mr. Pennant we have ventured to introduce this species. "Of these birds," says Mr. Pennant, in the appendix to the British Zoology, "we have heard of only two being seen at large in our Island; one was shot near *Helfton-bridge, Cornwall*, and an account of it transmitted to us by the Reverend Doctor *William Borlase*."

These birds are frequent in most parts of *Europe*; in *Germany*, *Sicily* and *Malta* they are so common as to be sold in the markets \*. *Edwards* mentions one shot on *Gibraltar Rock*; it is also met with from the southern parts of *Russia* to the neighbourhood of the *Irtish* †.

It makes its nest in woods, most frequently in *Birch trees* ‡; never lays more than five eggs, which are of a clear green, sprinkled with innumerable dark specks §. It does not come to its colour till

\* *Willughby.*

† *Art. Zool.*

‡ *Frisch.*

§ *Latham.*

## P L A T E XXXIII.

the second year; flies in troops in autumn, and is often seen in tilled ground, with rooks and other birds, searching for worms, small feeds, and roots ||; it feeds also on frogs and beetles ¶.

By one author it is said sometimes to make the nest in holes in the ground, in one of which two eggs were found \*\*; by another, it is observed never to be seen on the ground ††.

“It is remarkable for making a chattering noise; from which it is called by some *Garrulus*.” *Pennant*.

## LE GEAY BLANC.

### WHITE JAY.

*Bris. av. 2. p. 51. A.*

---

In the description of *CORVUS GLANDARIUS*, COMMON JAY, we mentioned the specimen from which our present figure is taken; it was found in a nest with four other Jays of the common sort, and can only be considered as a variety.

We have introduced it into this work, as a solitary example how far the plumage of birds will sometimes vary from local circumstances.

*Lath. Gen. Syn. I.* 124. *Suppl.* 43.

SHORT-EARED OWL. *Amer. Zool.*

---

Length fourteen inches, breadth when the wings are extended three feet, weight fourteen ounces.

Mr. Pennant appears to be the first author who has described this species \*; he says it is a bird of passage, has been observed to visit *Lincolnshire* the beginning of *October*, and to retire early in the spring; he supposes its summer retreat is *Norway*. It conceals itself in the long grass in the day-time; when disturbed it will seldom fly far, but will light and sit looking at one, at which time the horns may be seen very distinctly. Mr. Pennant further adds, "it is found frequently on the hill of *Hoy* in the *Orkneys*, where it flies about and preys by day like a hawk. I have also received this species from *Lancashire*, which is a hilly and wooded country, and my friends have also sent it from *New England* and *Newfoundland*." *Penn. Br. Zool.*

---

\* Mr. Latham has made this severe, though not entirely unmerited animadversion on the remarks of M. de Buffon, in *Hist. des Ois.* Vol. I. p. 353, note (a) "M. de Buffon seems to think that this bird is the *Scops*, than which no two species differ more. We have not the *Scops* in *England*, neither do I think the above-described bird to be a native of *France*. It would therefore have appeared candid in the abovementioned author, to have suspended his opinion of the matter till he had been better informed, as he seems to bear somewhat hard upon Mr. Pennant, who, I am clear, is the first who has described it."—*Gen. Syn.*

Dr. Forster

## PLATE XXXV.

Dr. Forster gave it the specific name *Brachyotos*, in the *Philosophical Transactions*; he says it is called *Mouse Hawk* at *Hudson's Bay*. It visits that part in *May*, and makes a nest of dry grafs on the ground: The eggs are white; it departs south in *September*; is called by the natives *Thothofecausew* †. It is very common in the northern and woody parts of *Siberia* †.

Is known in *England* by the name of *Woodcock Owl*, as it is supposed to perform its migrations with the *Woodcock*. Feeds on mice.

This is the smallest European species of the Woodpecker genus we have any knowledge of at this time ; its length is six inches, breadth eleven inches, and weight one ounce.

It visits orchards, and feeds on the larva of insects, which it sometimes pecks out of the trunks of trees or decayed wood. It builds in an hole of a tree. Our figure represents the male ; the female has the crown of the head white.—This species is not commonly met with in *England*.

*Buffon* says it inhabits most of the provinces of *France*\*, and *Linnaeus* observes it inhabits the higher parts of *Asia* ; it is said also to be seen as far north as *Denmark*, *Russia*, and *Siberia*.

*Pennant* remarks it has all the characters and actions of the greater kind, but is not so often met with.

---

\* *Salerne* denies its being found in France. *Orn.* p. 107.

This species is thirteen inches in length, weight six ounces and an half. The female has no red mark on the lower jaw; Frisch and Klein observe they have no red on the crown of the head; but Latham, in his Synopsis of Birds, says, he has had them when they could scarcely fly, the red was then mixed with brown, but became full red after the first moult.

It is common in many parts of *Europe*, and is found as high north as *Lapmark*; in *England* it is met with in most woody places.

They build in the hollow trunks of trees, fifteen or twenty feet from the ground: with their bills, which are very strong, hard, and formed like a wedge, they can bore through the living part of the wood, till they come to that which is rotten; the hole thus formed is

## PLATE XXXVII.

as perfectly in the form of a circle as if made with the assistance of a pair of compasses, and is hollowed out to a proper depth before the eggs are deposited. They lay generally five, sometimes six \* eggs; the young birds climb up and down the trees before they can fly.

According to *Pennant* the eggs are of a beautiful semitransparent white; greenish, with black spots, *Latham*; and greyish or yellowish white, marked with irregular pale yellow brown lines in the figure of the egg in *Sepp's* plate †.

It feeds on Insects, which it sometimes extracts from beneath the bark of trees, or from the solid wood by means of its strong, though slender barbed tongue; is said to make great havock among bees.

In the Leverian Museum there is a variety of this species, entirely of a straw colour, except the crown, which is faintly marked with red. It was shot at *Belvoir chaise*.

Length twenty-one inches, breadth thirty-three inches, weight two pounds. We have represented the male, the female has only the rudiment of a crest: the head and upper part of the neck, dull ferruginous: chin white: fore part of the neck and the breast ferruginous, mottled with black and white: upper part of the neck, back, rump, and scapulars, cinerous: the lower part of the breast and belly white.

Both male and female are very liable to variation in the colour of their plumage; in some the white space on the neck is much more diffused than in others; the same has been observed of the portion of  
white

## PLATE XXXVIII.

white on the wings; and the females differ in the brightness of their colour frequently.

Mr. *Latham* mentions a specimen which was shot near *Sandwich* in *Kent*; but it is chiefly found in the northern parts of *Great-Britain*; it is observed to breed on *Loch Mari*, in the county of *Ross*, and in the *Isle of Ilay*\*.

The nest is made of withered grass, and is lined with the down of the bird's breast; it lays from eight to thirteen eggs, like those of a wild duck, but smaller and whiter; the young are of a dirty brown like gollings†.

It is found in most of the northern parts of *Europe*, in *Russia*, about the great rivers of *Siberia*, and the lake *Baikal*; also frequent in *Greenland*, where it breeds on the shores; in *Newfoundland* and *Hudson's Bay*.

The length of this bird is six inches and three quarters; it is distinguished from other species of the same genus by the very singular structure of its bill, both mandibles of which curve across each other. The male is generally of a fine orange red inclining to rose-colour, mixed more or less with brown, the female of a dull green; but both sexes are very liable to variations: the male is sometimes of a yellowish orange; of a deep red; or even inclining to a dark purple hue, intermixed with yellow, red, brown, green, &c. the female varies also, but seldom acquires more than a dull intermixture of other colours on the olive-green according to the different seasons. The males are like the females when young, and gradually change to a fine red.

Mr.

## PLATE XXXIX.

Mr. Pennant says there are two varieties of this species, our present specimen, and another which is very rare; of the latter he says he received a male and female from Shropshire; they were superior in size to the former, the bill remarkably thick and short, more incurvated than that of the common kind, and the ends more blunt \*.

The Cross-bill is common in *Sweden*, *Germany*, and *Switzerland*; is found also in *Russia* and *Siberia*, in *North America*, *Greenland*, &c. It is not supposed to breed in *England*, but to visit us generally in small flocks, though it has been seen in vast multitudes in some seasons. As the seeds of the Fir, or Pine, is their natural food, they always retire to forests where those trees grow in most abundance: they feed also on Hemp-feed; and are said to do great damage in orchards, by tearing the apples to pieces to eat the pips or seeds.

It is observed, in *North America*, to build its nest in the highest part of the Fir-trees, fastening it to the branches by the resinous matter which exudes from the trees †.

Three kinds of Wagtails are found in this country, the Common, or White, the Yellow, and the Grey; the two former we have already figured; the latter is a very elegant bird, and appears to be the rarest of the three species, it breeds in the north of England; supposed not nearer than *Cumberland*\*, and departs southward in October.

In the male only the chin and throat are black. Length seven inches and an half.

All the birds of this genus frequent watery places; are very lively, and have a brisk motion in their tails. They feed on Insects. The nest of the Grey Wagtail is made on the ground; it is composed of dried fibres and moss, lined with wool or feathers within; it contains from six to eight eggs, of a dirty white, marked with yellow spots.

Gjok.	<i>Faun. Succ. sp.</i> 96.

---

The earliest appearance of the Cuckow in this country is supposed to be in *February* \*, it is rarely in *March*, but more commonly in *April*: it has been emphatically called the harbinger of Summer, or the messenger of Spring; and its note, when heard early in the year, should never fail to invite the rural œconomist to his useful occupation. With *Stillingfleet* and *Pennant* we acknowledge the fallibility of human Calendars, for the purposes of husbandry; and with them must conclude, that “some attention should be given to those feathered guides, who come heaven-taught, and point out the true commencement of the season; their food being the Insects of those seasons they continue with us †.”

The Cuckow is so well known in this, and every other country of *Europe*, that we are not surprised to find its Natural History has engaged the particular attention of every writer on Ornithology, in whose works it could be introduced with propriety: it may hence be difficult, if not impossible, to treat of its peculiar habits with an elegance of language superior to the description of *Buffon*, to select more judiciously the beautiful fictions of Antient Bards, than has been done by *Pennant*

---

\* Mentioned in Br. Zool. Pen.

† Br. Zool.

## PLATE XLI.

and other preceding writers; who have thus embellished its history; or to add to general information any material circumstance that has evaded the vigilance and accuracy of *Latham*.

The note of this bird is a call to love, and is peculiar to the male; who, perched on the branch of a tree, or the summit of an eminence, thus invites the female from the coppice in which she sits in silence: in a calm evening his note may be heard among the trees far off; and when disappointed of its mate, the neighbouring woods reecho his hollow note at the distance of a quarter of a mile.

All Authors have allowed that the Cuckow does not hatch its own eggs, but deposits them in the nest of some other bird, generally in that of a Hedge-Sparrow, Water-Wagtail, or a Yellow-Hammer; some Writers say the Cuckow lays only one egg, others two \* in the nest; the foster-parent attends them with the same care as her own, and when the brood is hatched, she shews no dislike to the spurious offspring; she treats them with equal tenderness, and toils with the same assiduity to supply them with food; the young Cuckow, when fledged, follows its little instructor for a short time; but as its appetite encreases, and the small Insects it collects, in imitation of its supposed parent, soon become insufficient for its subsistence, they separate. Its ingratitude is proverbial among the *French* †, from a ridiculous supposition that it changed into a Hawk, and devoured its nurse.

About the end of *June* the call of the male ceases, though it does not take its final departure till the end of *September* or beginning of

---

\* The egg figured by *Sepp* is like the Jackdaw's, both in size and shape, of a greenish white, speckled with brown.—*Latham* says it is certainly not that of the Cuckow, which he describes not much bigger than that of the Hedge-Sparrow, greatly elongated in shape, the ground colour not unlike it, and mottled all over with ferruginous purple.

† “Ingrat comme un Coucou.”

## PLATE XLI.

*October.* Latham observes he has heard it call at midnight more than once or twice in the course of the Summer, and adds it was bright moon-light every time.

They feed on Insects, flesh, &c. in the stomach of several that have been dissected the Caterpillars of the Fox \* and Buff-tip † Moth have been found; in others vegetable matter, egg-shells, Beetles, &c.

They are supposed to migrate to *Africa* and *Aleppo*, and to visit several countries in their passage; and are known in the northern parts of the world, even to *Kamtchatka*.

*Le Coucou roux*, of *Briffon*, is a variety of a young bird, having the upper parts varied with rufous, where the other is white. Birds of the first year are very liable to variation, scarce two being found alike; the bars are much more numerous in some than in others, and the ground colour more or less varied with ferruginous, according to the age.

On dissection, the stomach has been discovered to be very capacious and long; protruding far beyond the *sternum*, that part being so very short, as not to be sufficient to take off the pressure in incubation, whereby digestion may be impeded. This has been assigned as the reason why it does not hatch its own eggs.

Length of the adult bird is fourteen inches, breadth twenty-five inches, weight two ounces and an half.

The Male of this species is about nine inches in length; its weight four ounces; the Female is rather larger, the colours are in general more obscure, the white stripe over the eye is narrower, the black on the belly is intermixed with white, and the white line across the breast is wanting.

They are found in plenty in some parts of *England*, in others are unknown. Are most common in *Cambridgeshire*, *Lincolnshire*, and *Derbyshire*, about the latter end of *April*, in *May* and *June*; during which time they are very fat, and are much esteemed for their delicate flavour. In *April* and *September* they are taken on the *Wiltshire* and *Berkshire* downs \*: they are also seen on the sea side at *Meales*, in *Lancashire*, in *April*; where they continue about three weeks; from thence they remove northward to *Leyton Haws*, where they stay about a fortnight †. It is supposed that they breed in the mountains of *Cumberland* and *Westmoreland*, as they appear there in *May*, and are observed there after the breeding season. They breed also on several of the Highland hills \*. Are proverbially stupid birds, and easily taken in a net, or shot.

\* *Latham.*

† *Pennant.*

## PLATE XLII.

*Le Guignard d'Angleterre* of *Brisson* \* is considered as a variety of this species; the weight and size correspond with the former description; but the fore part of the Neck, Breast, Belly, Sides, and Thighs, are pale yellow and white mixed, the Tail white, except the two middle feathers, the Legs and Feet of a sordid green. *Albin* has figured this bird; he says he received it from *Lincolnshire*, by the name of Dotterel †.

Those birds are common in the northern parts of *Europe*; *Linnaeus* says they are frequent in the *Lapland Alps*, and that they visit *Sweden* in *May*. Breed in the northern parts of *Russia* and *Siberia*.

Dieschk	<i>Scop.</i>
Stenckneck.	<i>Faun. Suec.</i>
Kernbeis, Nusbeisser.	<i>Kram.</i>

\* This beautiful bird is rarely met with in this country except in winter; it is only an occasional visitor with us, though in *France* it is not uncommon; and in *Germany, Italy, Sweden*, and the southern parts of *Russia* it is very plenty. It has been seen in *England* in the summer months once or twice, and *Latham* seems inclined to believe they may sometimes breed here.

They feed on berries, and on the kernels of cherries, almonds, haws, &c. their bills are very large, and so strong that they are able to crack the hardest stones of any fruit with the greatest facility.

## PLATE XLIII.

They are said to build the nest in hollow trees; or between the forked branches, about twelve feet from the ground; it is composed of small dry fibres, intermixed with liver-wort; they lay five or six eggs\* of a roundish shape, of a bluish green, spotted with olive brown, and interspersed with a few irregular black markings according to *Latham*; in the figure given by *Sepp* the eggs are of a pale purple colour, spotted with brown; the nest appears of a loose texture, and is placed on an oak.

The length of this species is seven inches, breadth thirteen, weight two ounces; the colours of the Female are not so bright as those of the Male, and the space between the bill and the eye, which is black in the latter, is grey in the other sex.

The general description we have given of its colours must not be supposed to constitute its distinguishing character: they vary exceedingly in different specimens; in some the bill is almost black, the crown of the head in some is whitish; in others wholly black: sometimes the white band across the wing inclines to grey; in others no trace of white can be perceived: it has been seen with the body wholly black, and *Scopoli* mentions one entirely white, the quills excepted.

---

\* Willughby.

# PLATE XLIV.

## PODICEPS\* NIGRICANS.

### DUSKY GREBE.

#### ANSERES.

Bill obtuse, covered with a thin membrane, broad, gibbous below the base, swelled at the apex. Tongue fleshy. Legs naked. Feet webbed or finned.

#### GENERIC CHARACTER.

Bill strong, slender, and sharp pointed. Nostrils linear. Space between the eye and bill bare of feathers. Tongue slightly cloven at the end. Body depressed: feathers thick set, compact, and very smooth and glossy. Wings short. No tail. Toes furnished on each side with a broad plain membrane.

#### SPECIFIC CHARACTER,

#### AND

#### SYNONYMS.

Bill black. Lore and irides red. Upper parts of the head, neck, and body dusky brown, beneath silvery white. Legs dirty olive.

---

\* We have had occasion in a former description to mention the alteration made by *Brissón* in the *Colymbus* genus of Ray and Linnæus; and since adopted by our English ornithologists, *Pennant* and *Latham*. In the Linnæan genus are included the *Grebes*, *Guillemots* and *Divers*, which as they differ materially in the form of their feet, have been separated by those later authors into distinct tribes.—Podiceps is the new generic title given by *Latham* to the Grebes.

---

The Golden Plover is found in small flocks on our moors and heaths, in the winter season; it is not a common species in this country. It breeds on several unfrequented mountains, particularly on those of the *Isle of Rum*, and the loftier *Hebrides*\*: and on the *Grampian*, and all the heathy hills of the islands, and *Highlands* of *Scotland*†.

It is an inhabitant of Sweden, Denmark, Lapland, and other countries towards the frozen ocean; and according to *Ruffel*‡ extends to the south as far as Aleppo.

It lays four eggs, sharply pointed at the lesser end, two inches and one-eighth in length, of a pale cinereous olive, blotched with blackish spots§.

In some specimens the belly is black, in others black intermixed with white; this is entirely owing to the season; early in March the black on the breast is first seen, it increases till that part becomes full black; but after the time of incubation that colour disappears. Instead of a hind toe some have only a small claw.

This species is the most common of all the gulls. It breeds on the rocks and cliffs on our shores and rivers which are contiguous to the sea, and is seen in vast numbers on the Thames in spring and winter, picking up the small fish, worms, &c. left by the tide.

It is seen as far north as *Iceland*, *Lapland*, and the *Russian Lakes*, and also on the coast of *Newfoundland*. It is an inhabitant of the warmer climates of the south, as *Greece*, some parts of *Italy*, and most of the shores of the *Mediterranean Sea*.

The length is seventeen inches: breadth thirty-six inches, and weight one pound. The eggs are two inches and a half in length; of a deep olive brown, marked with irregular deep red reddish blotches\*.

They differ a little in their markings: Mr. Latham mentions one, the head and half the neck of which were marked with short dusky streaks.

The Kite is very common in England, and is well known in several parts of the continent of Europe\*; but it inhabits the more northern countries only during the hottest months of summer. *Bosman* mentions it as a native of Guinea†; *Linnaeus* also says it inhabits Europe, Asia, and Africa. No author has yet described it as a native of America.

It breeds in woods. The nest is formed of different materials; the outside of sticks, the lining of rags, bits of flannel, rope, paper, &c‡. It lays two or three eggs, which are roundish, and of a whitish colour, spotted with dirty yellow. The egg of the Kite is described by Mr. *Latham* (in his Supplement to the Synopsis of Birds) from the specimen formerly preserved in the Portland Museum; it was of a bluish

## P L A T E XLVII.

white, inclining to red at one end, blending itself with the white by small markings.

As a bird of prey, the Kite is known to be very destructive among poultry; it devours also small birds and animals, and Mr. Latham says it will sometimes eat fish, as it has been found feeding on the remains of one by the side of a pond, after having probably beaten off its first possessor.

The forked tail of the Kite distinguishes it from every other bird, and serves to direct its flight with the greatest precision. It sometimes appears suspended, and quite motionless at a considerable height, then glides with astonishing velocity through the sky, without the smallest apparent action of its wings. When it descends on small birds, it generally carries them off in its talons, to devour them.

The length of this bird twenty-six inches: breadth five feet. They differ very frequently in their colours. Mr. Pennant mentions a beautiful variety entirely of a tawny colour that was shot in Lincolnshire.

581. 2.

This elegant bird is commonly met with in marshy places, or near rivers where willows, reeds, and sedges grow. The nest is generally made among the reeds. It is composed of straw, and dried fibres of plants, lined with hair, and contains five eggs, of a dirty white colour, marbled with brown\*.

It feeds on flies, spiders, &c. which it finds on the willows, or among the rushes, where it conceals itself. It imitates the note of the swallow, sky-lark, house-sparrow, and other birds, in a pleasing but hurrying manner, and sings all night †.

Some authors have supposed that it leaves us before winter, but that is uncertain.

Length of this bird is six inches and an half.
